**CHRIS KERR, JEFF MILNE**

# Unit cube of evaluation

# The 2x2 table

Forecast	Y
	N

Event

Y	N
a	b
c	d

- Base Rate =  $a+c$
- Prob of detection (POD) =  $a/(a+c)$
- Prob of false detection (POFD) =  $b/(b+d)$
- False alarm ratio (FAR) =  $b/(a+b)$
- Success ratio (SR) =  $a/(a+b)$
- Bias (B) =  $(a+b)/(a+c) = SR/POD$

- Critical success index (CSI) =  $a/(a+b+c)$ 
  - $CSI = HM[POD, SR] / (2 - HM[POD, SR])$
- $$\phi = \frac{ad - bc}{\sqrt{(a+b)(c+d)(a+c)(b+d)}}$$
- $$F_{\beta} = (1 + \beta^2) \frac{(SR)(POD)}{(\beta^2 SR + POD)}$$
  - $\beta$  is weight of importance of POD to SR
  - Equivalent to Tversky index, related to GM

# Simple Decision Rule

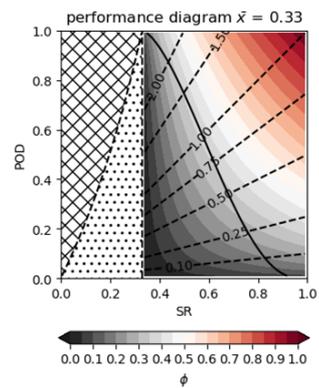

Forecast		Event	
		Y	N
	Y	A	B
	N	C	D

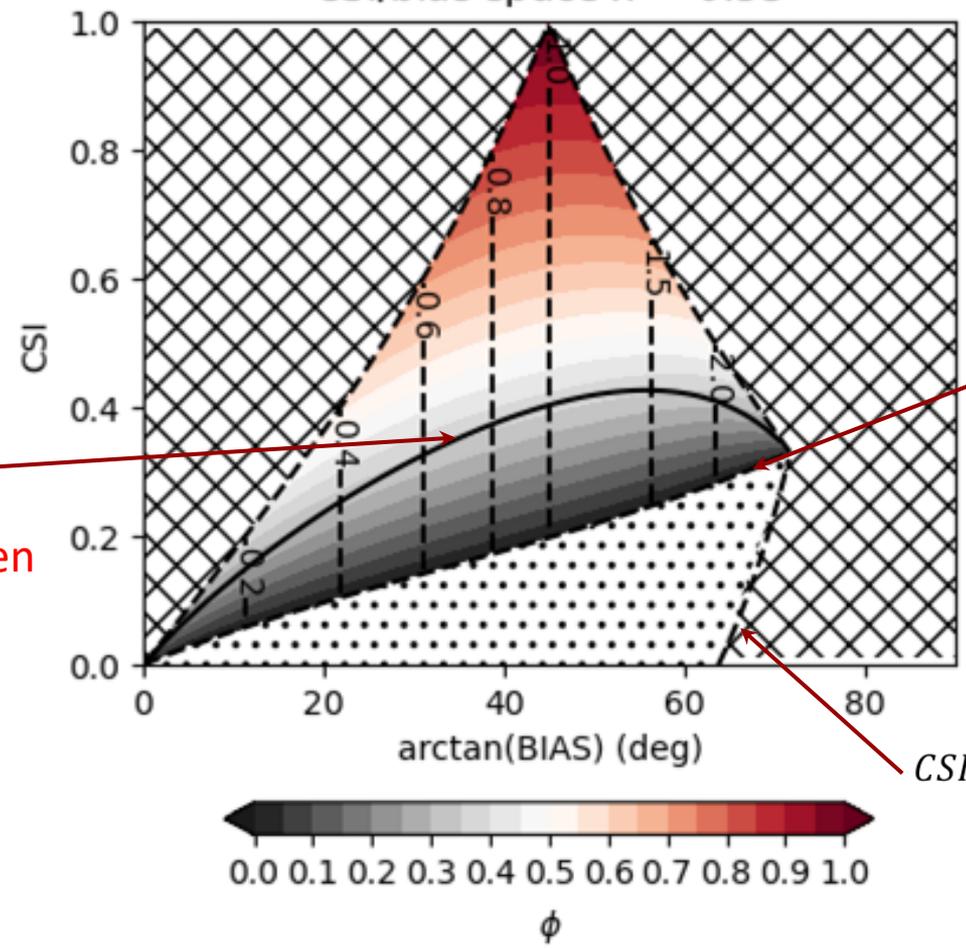

Misclassification Cost Ratio ( $\alpha$ ). Act if  $p > \frac{(B - D)}{(B - D) + (C - A)} = \frac{\text{Cost}(FA)}{\text{Cost}(FA) + \text{Cost}(ME)}$

$$\frac{\text{Cost}(FA)}{\text{Cost}(ME)} = \frac{\Delta POD}{\Delta POFD} \frac{\bar{x}}{1 - \bar{x}}$$

$$\bar{x} = 0.33$$

CSI/bias space  $\bar{x} = 0.33$

$d' = 1$

Forecast Less Often

$$CSI_{no\ skill} = \frac{B\bar{x}}{1+B-B\bar{x}}$$

Forecast More Often

$$CSI_{min} = \bar{x}(B + 1) - 1$$

# Our problem of interest

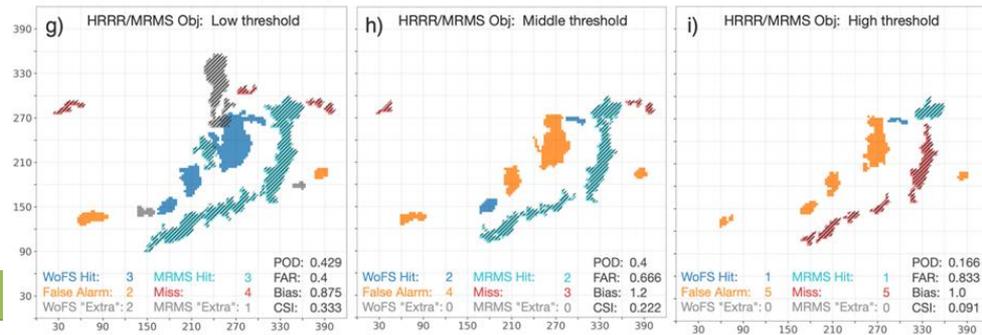

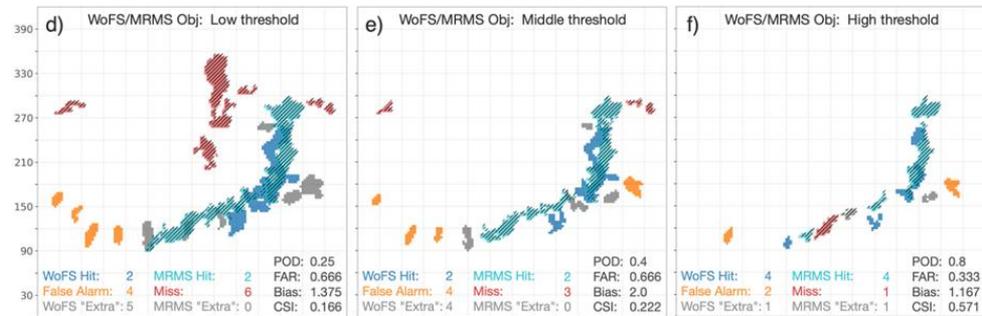

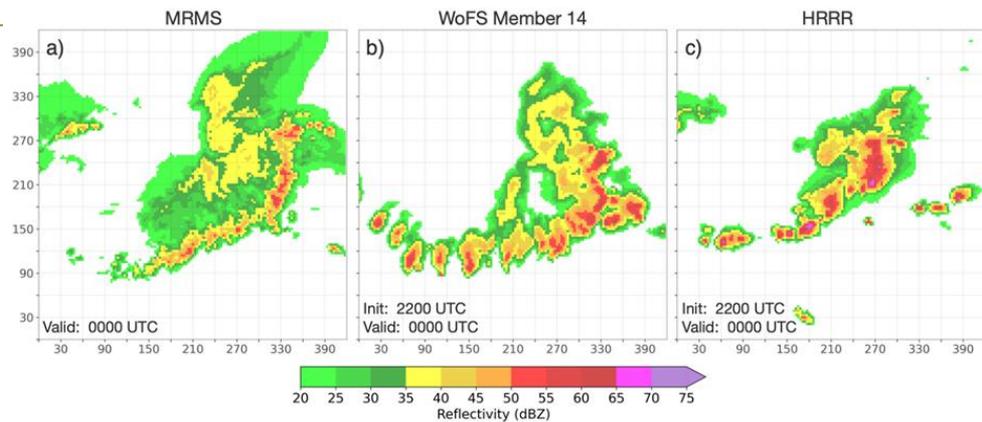

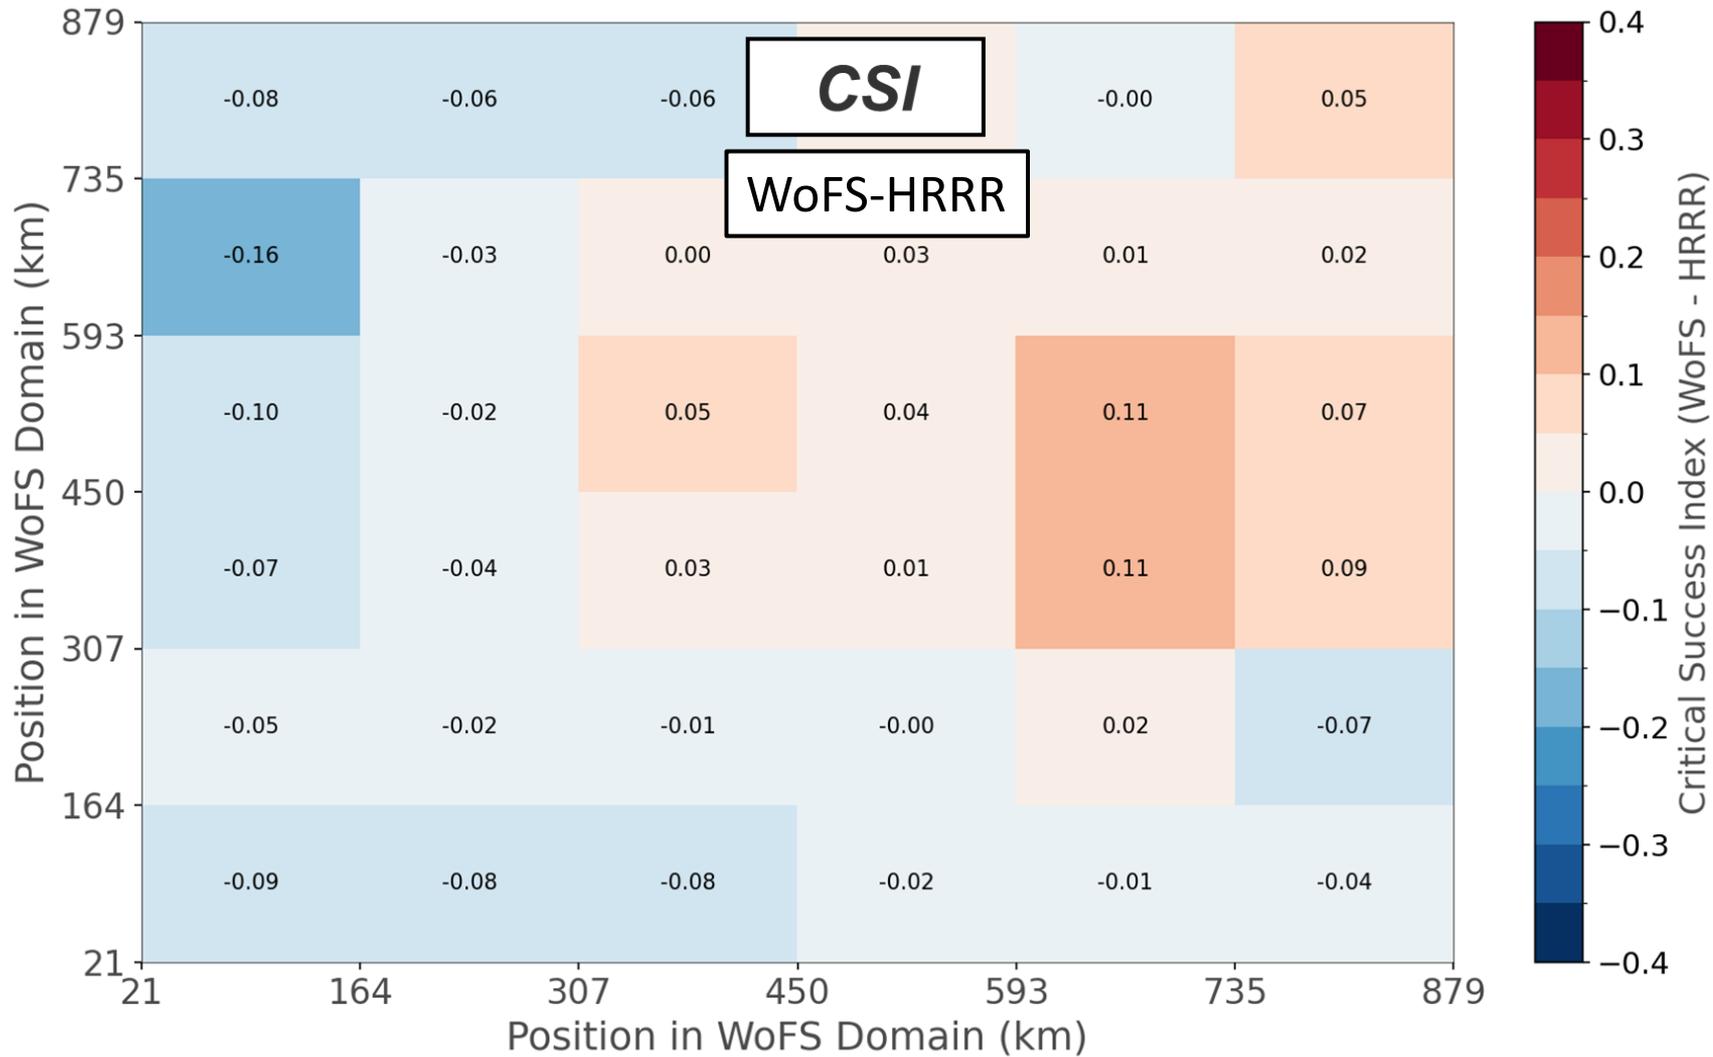

- Forecasting for severe thunderstorms, tornadoes  $\sim 0.5-6$  h
- Proxies for truth
- Can have deterministic, probabilistic systems
- Objects from Multi-Radar Multi-Sensor (MRMS)

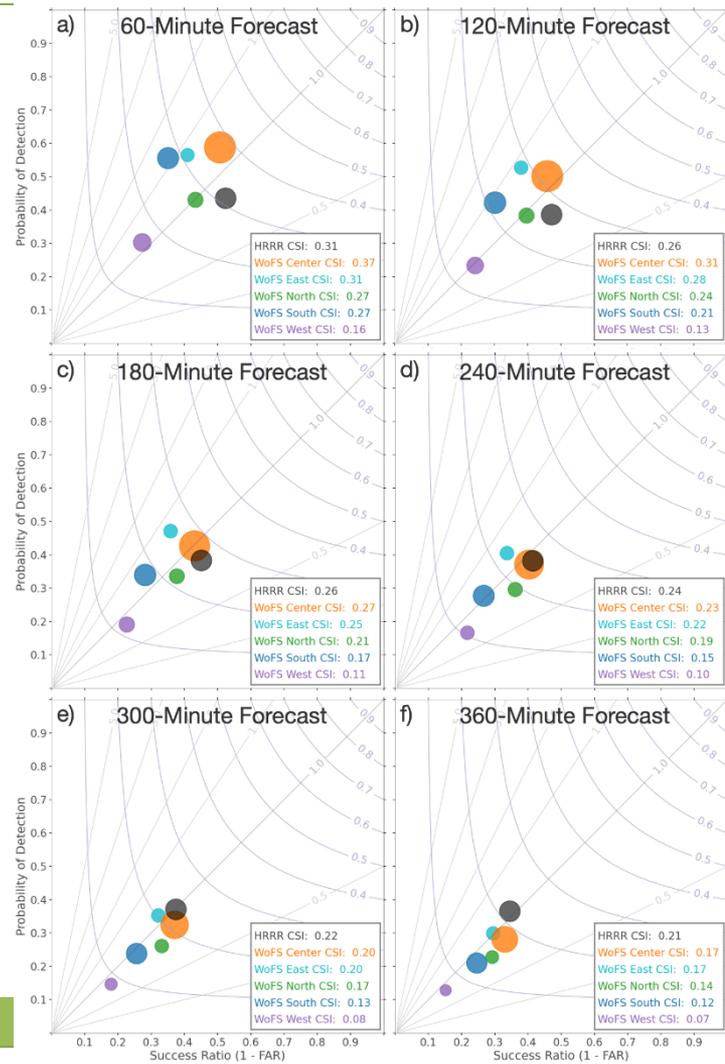

# Model description

- **HRRR (3 km)**
  - Covers contiguous US (1799x1059 grid points)
  - Runs out to 48 hours at 0000 and 1200 UTC
  - Hourly data assimilation
- **WOFS (3 km)**
  - Regional, moves around (300x300 grid points)
  - Uses HRRR 1200 UTC forecasts as initialization
  - Assimilates radar and satellite data not in HRRR every 15 minutes
  - 0-6 hr, available every 5 minutes, starting at 1700 UTC

# Comparing 1 and 3 km WOFs

- 1 km has smaller domain
- Compare only if both 1 and 3 have objects
- 30 minutes-3 hours, every 30 minutes

# Skill scores based on ROC, performance diagram elements

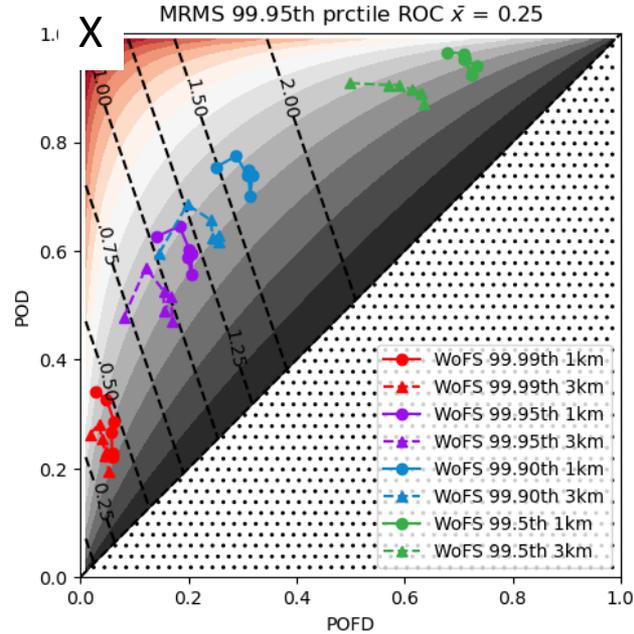

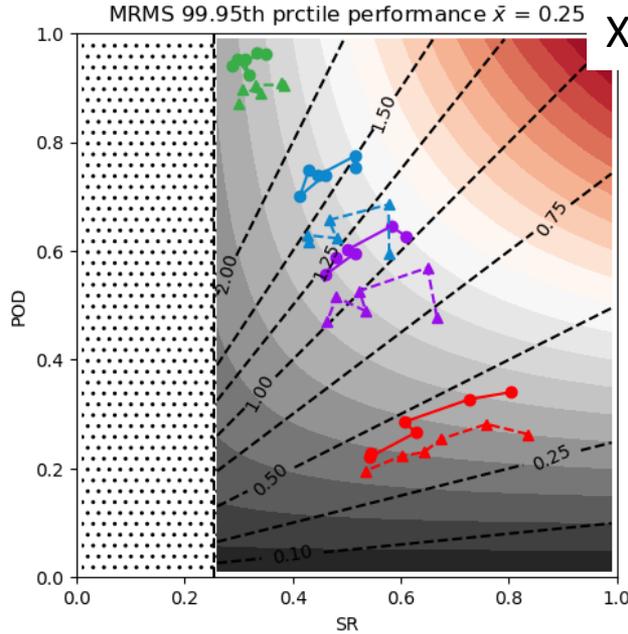

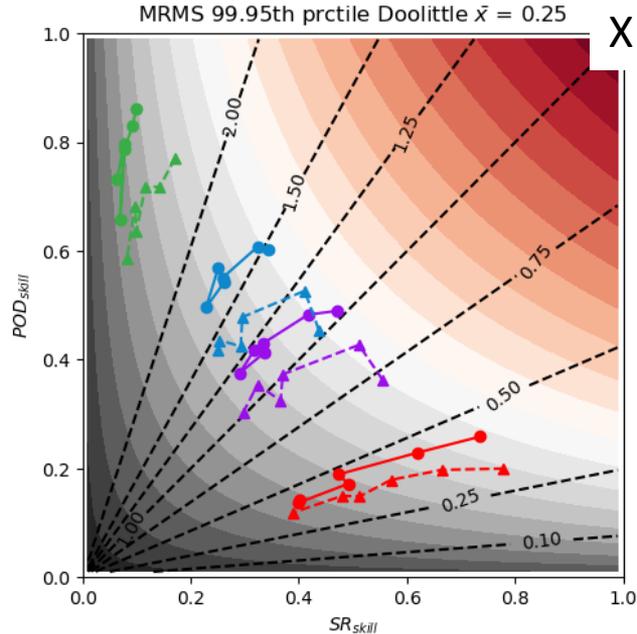

$$POD_{skill} = \frac{POD - POD_{chance}}{POD_{perfect} - POD_{chance}} = \frac{ad - bc}{(a + c)(c + d)}$$

$$SR_{skill} = \frac{SR - SR_{chance}}{SR_{perfect} - SR_{chance}} = \frac{ad - bc}{(a + b)(b + d)}$$

$$POFD_{skill} = \frac{POFD - POFD_{chance}}{POFD_{perfect} - POFD_{chance}} = \frac{ad - bc}{(a + b)(b + d)} = SR_{skill}$$

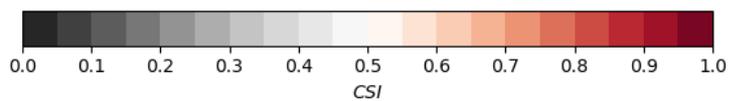

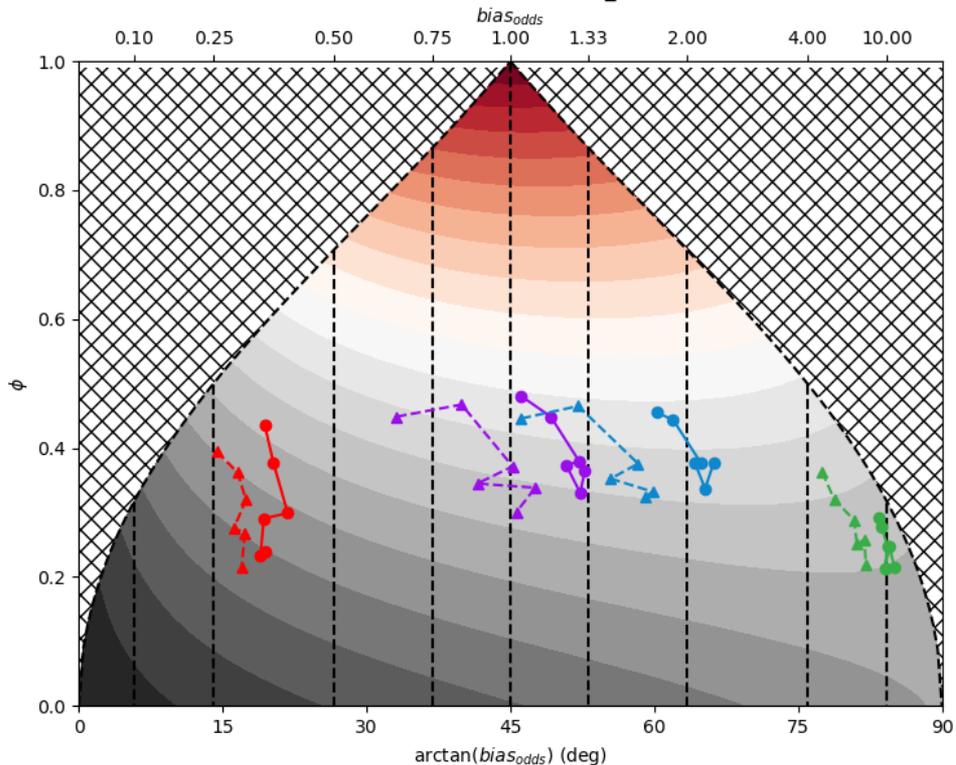

- Doolittle (1885), Kraemer (1988)

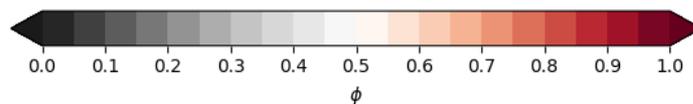

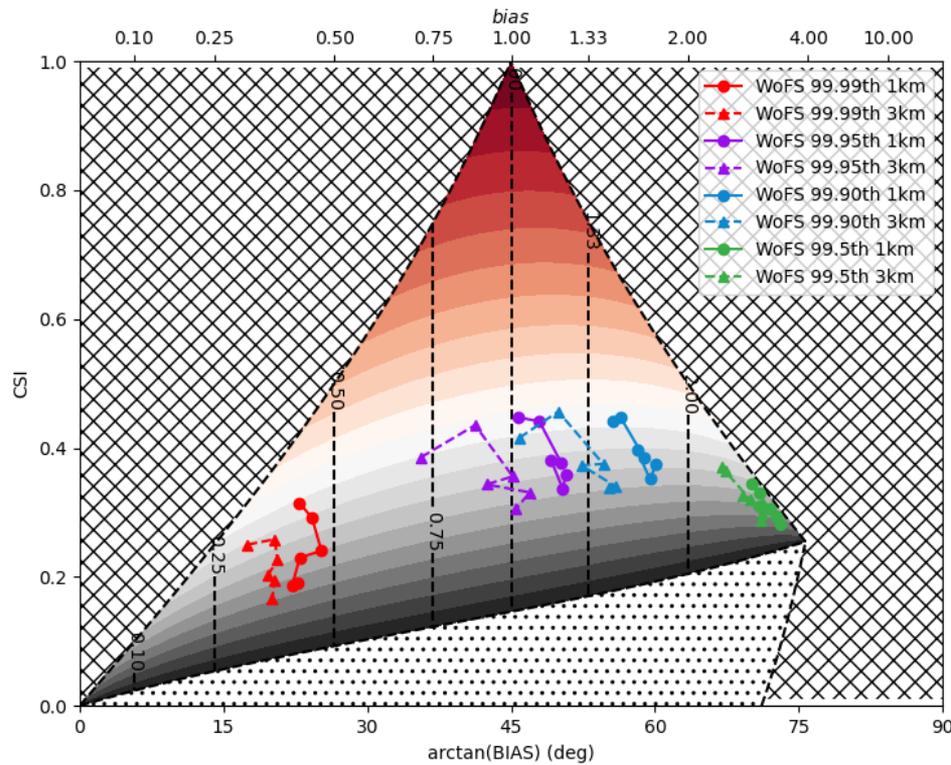

Solid-1 km, Dashed-3 km, X is perfect

Lines are same forecast threshold at different lead times (old-away from perfect)

MRMS 99.95th prctile correlation / bias\_odds space  $\bar{x} = 0.25$

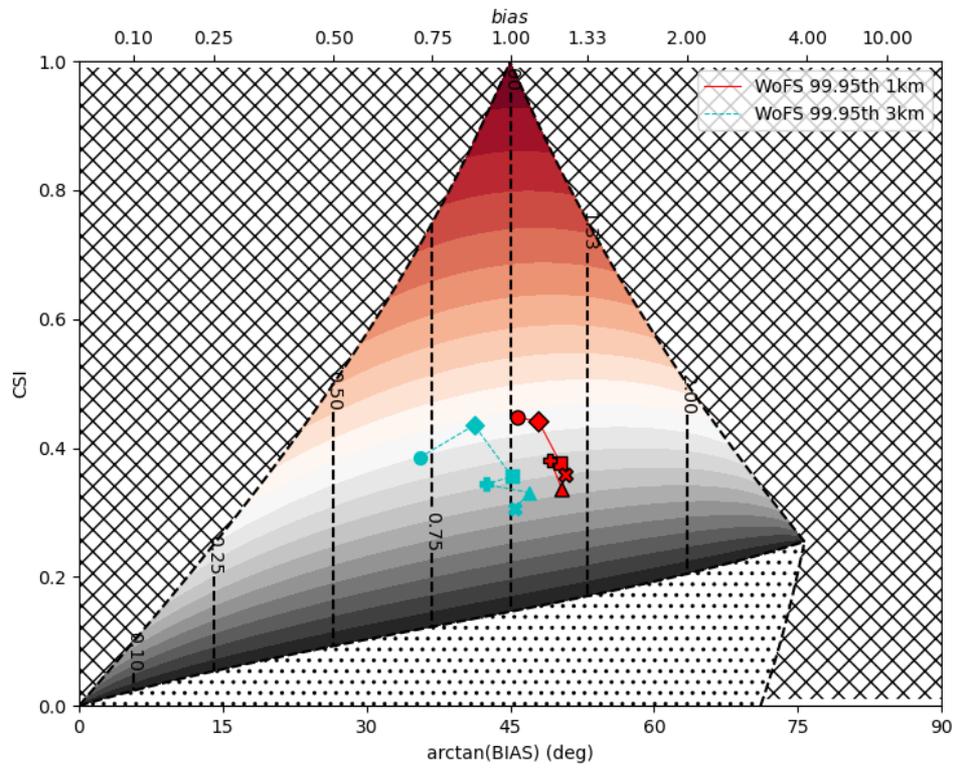

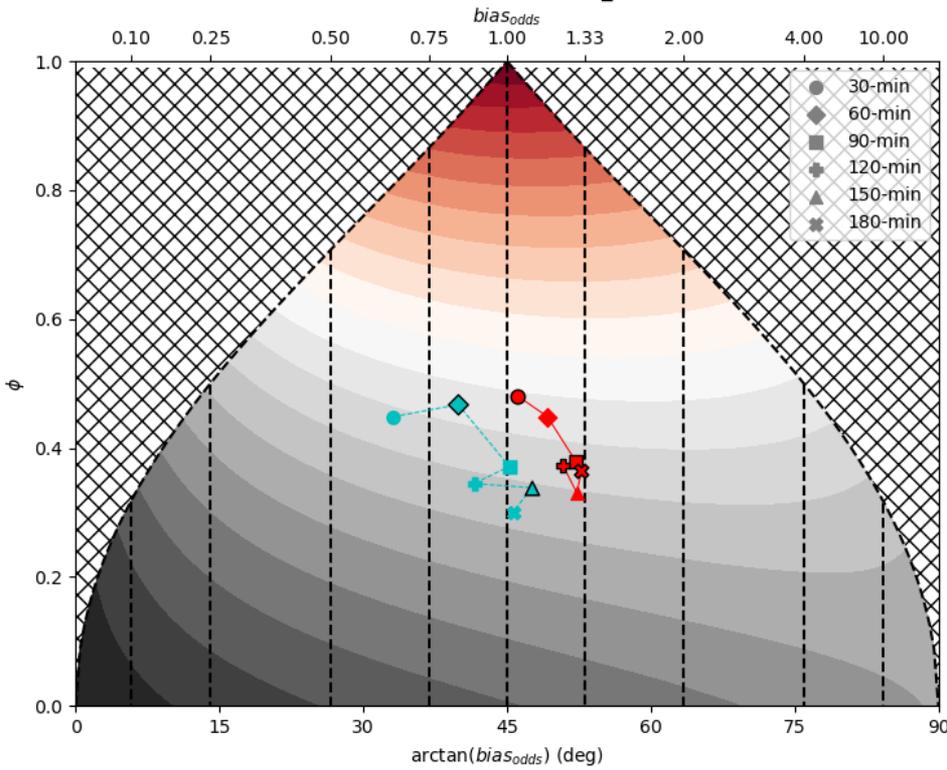

MRMS 99.95th prctile CSI/bias space  $\bar{x} = 0.25$

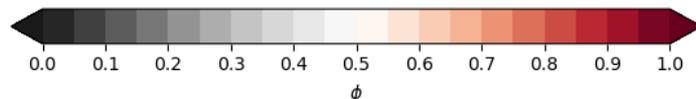

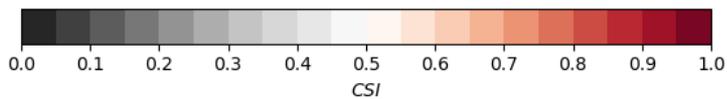

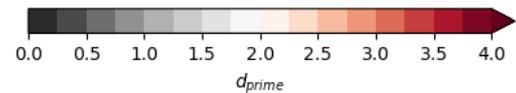

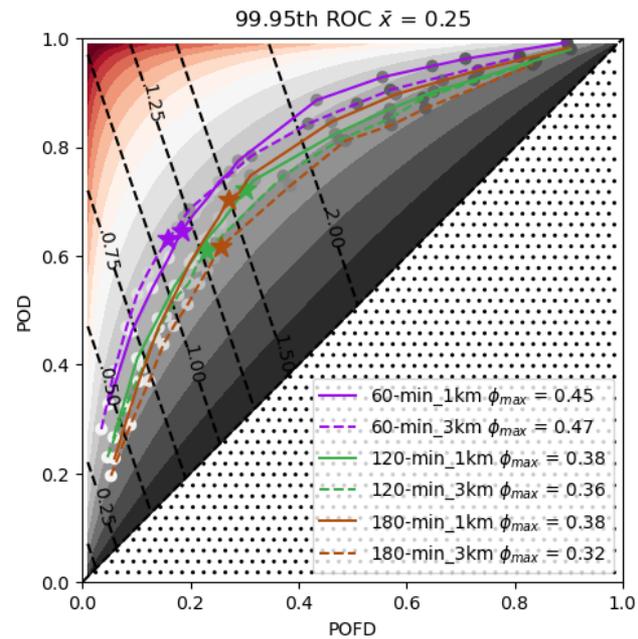

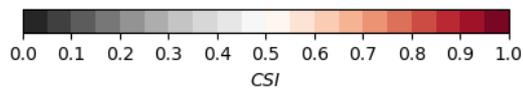

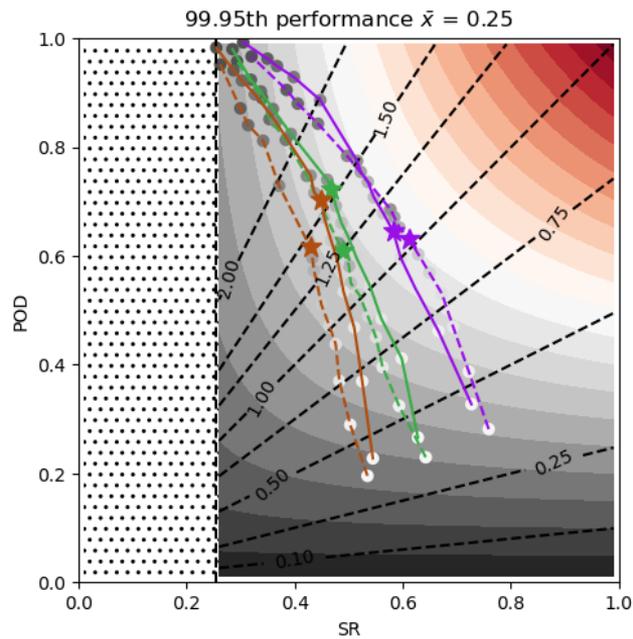

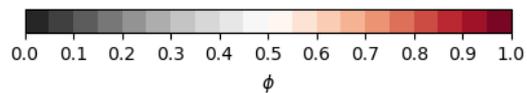

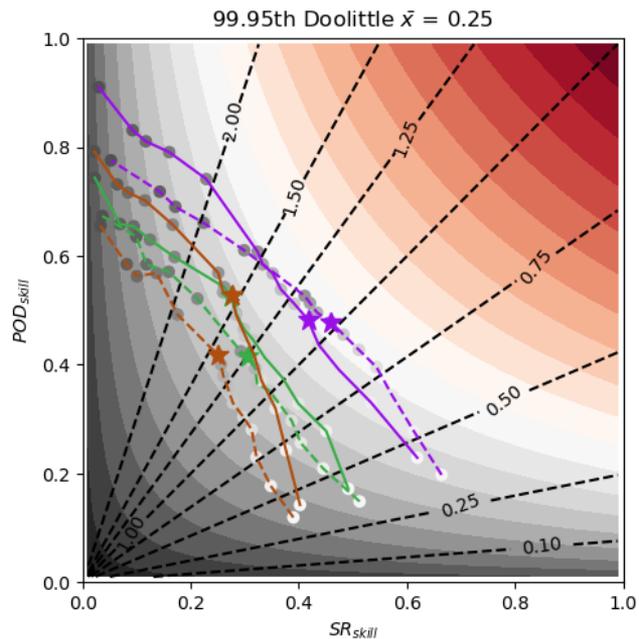

MRMS 99.95th prctile correlation / bias\_odds space  $\bar{x} = 0.25$

MRMS 99.95th prctile CSI/bias space  $\bar{x} = 0.25$

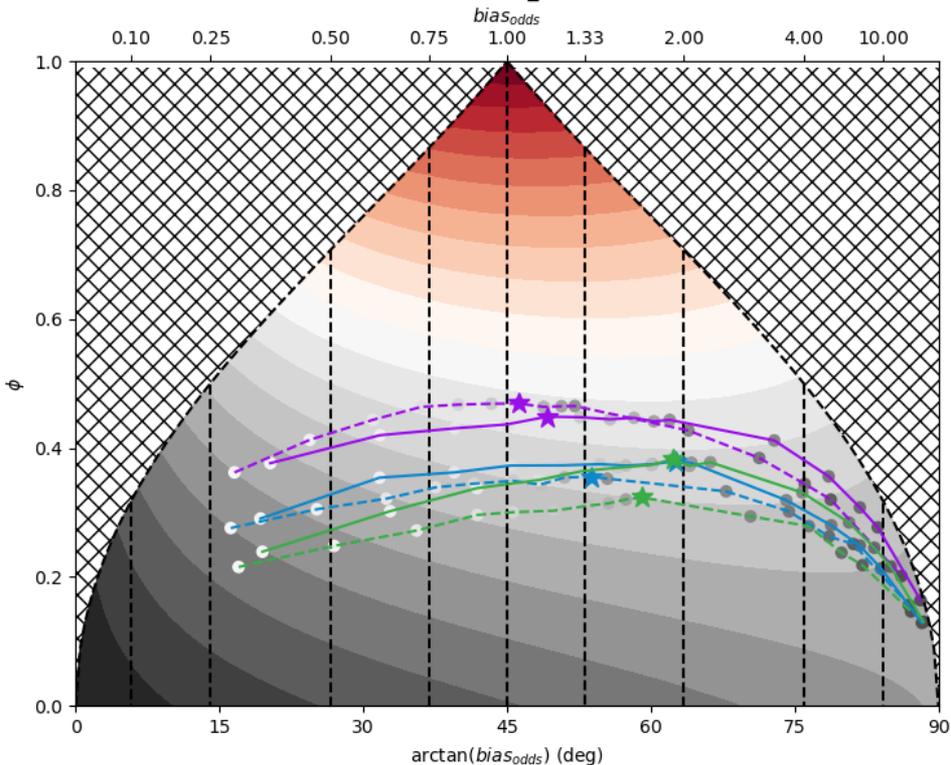

Using same forecast threshold as observed

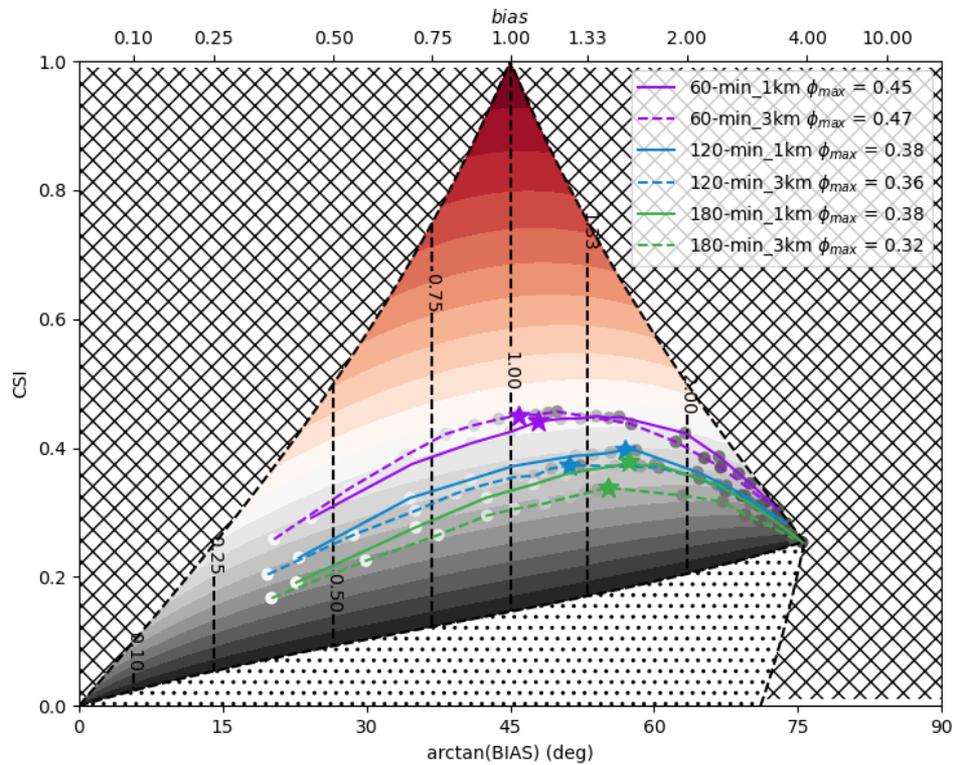

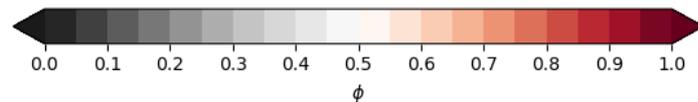

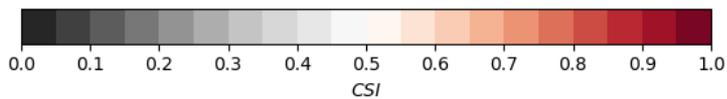

99.95th correlation / bias\_odds space  $\bar{x} = 0.25$

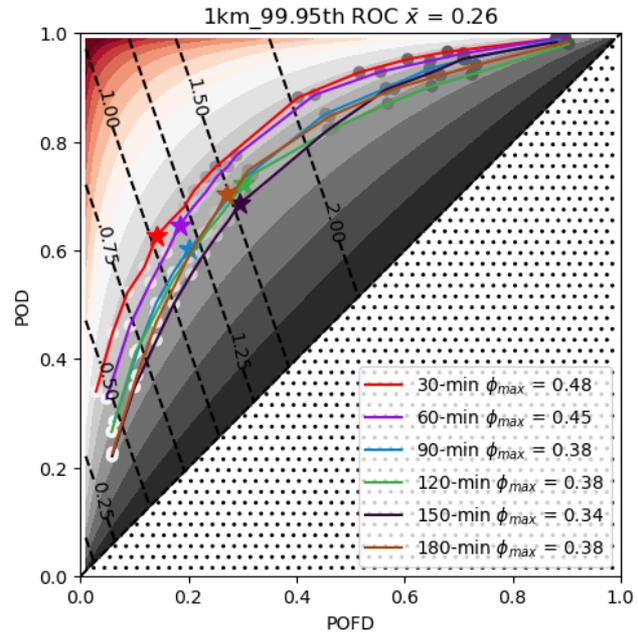

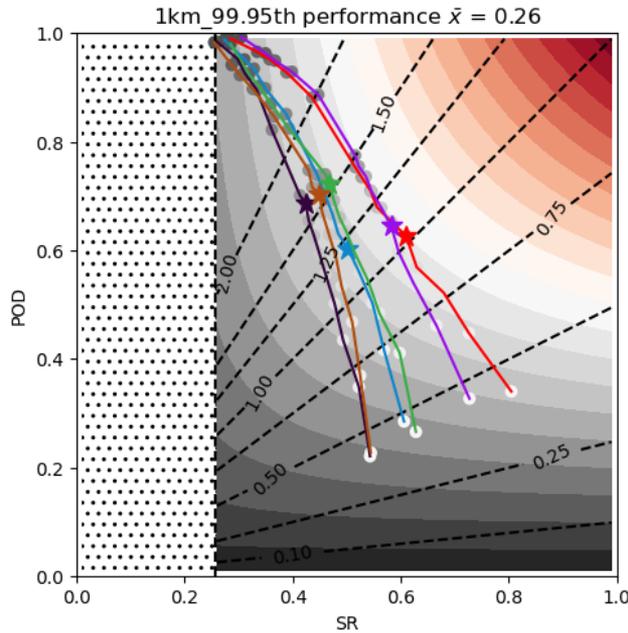

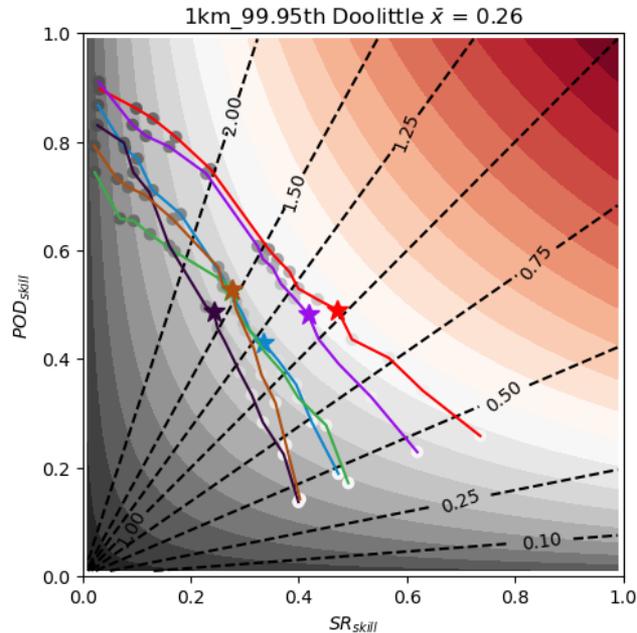

99.95th CSI/bias space  $\bar{x} = 0.25$

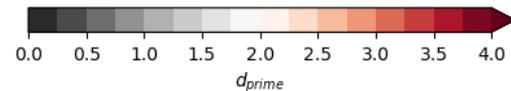

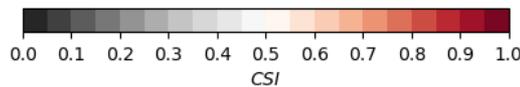

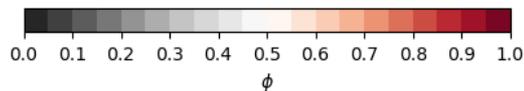

All forecast thresholds at one time

Only 1 km forecasts, every 30 minutes

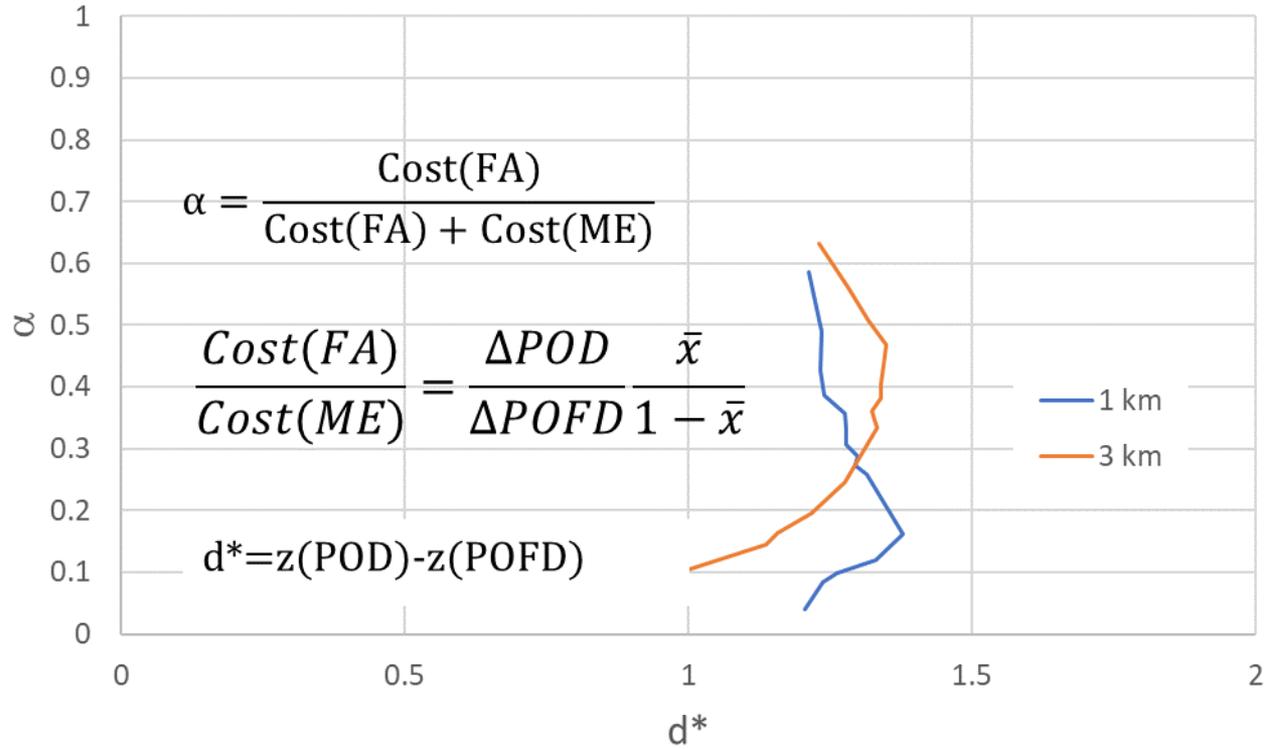

# Value propositions

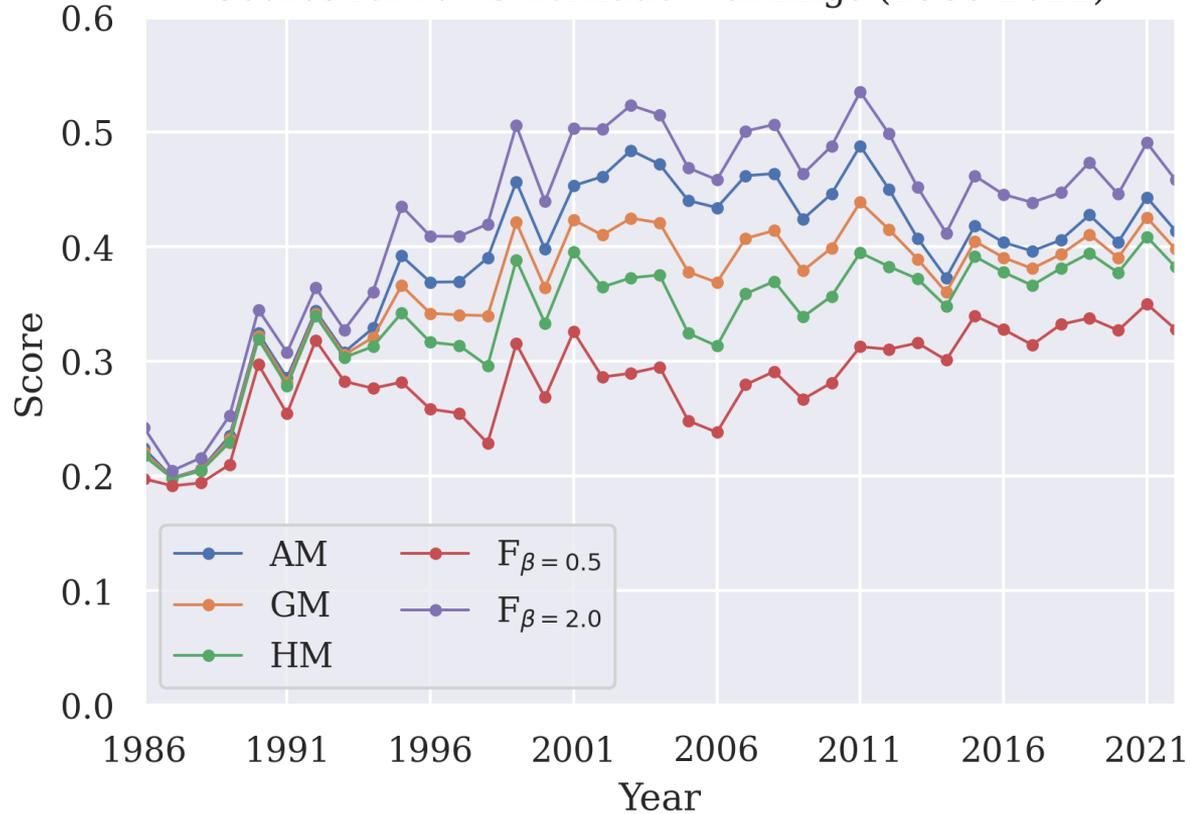

- CSI assumes errors are of same importance
  - Note shape of HM and GM has scores far from  $B=1$  look different
- F and Tversky explicitly weight errors
- Implicit vs explicit value of errors

## Quality-Decision Threshold

Scores for NWS Tornado Warnings (1986-2022)

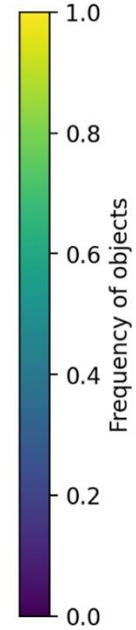

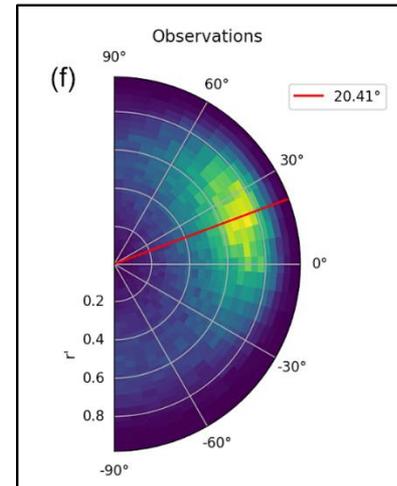

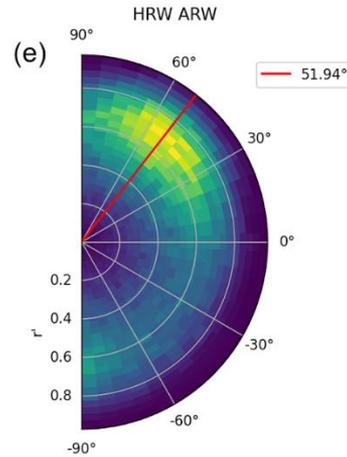

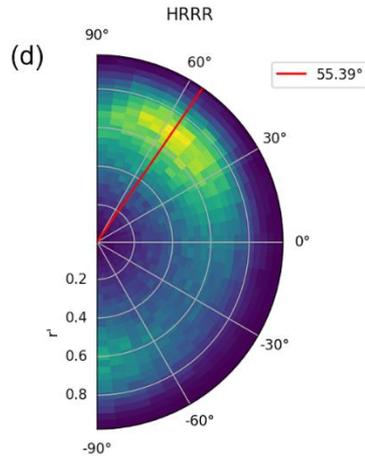

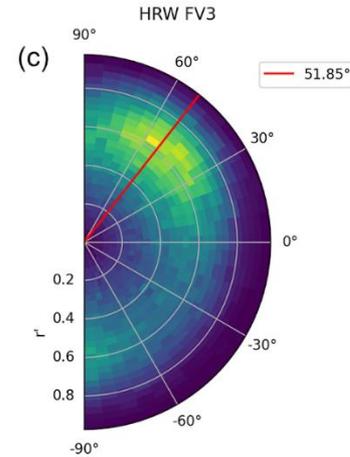

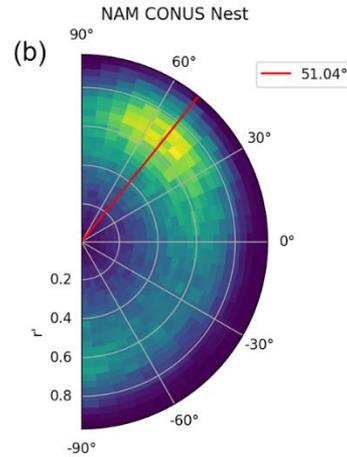

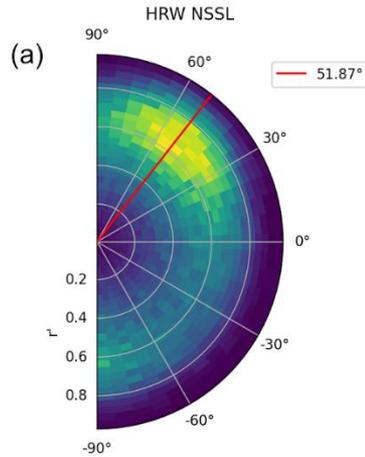

# Climatology of models

- Do models look like observations?
- Radar reflectivity from operational models

# Aspect ratio v orientation

# Wrapping Up

- Variety of graphics show variety of quality/value aspects
- Acknowledge choices
- Climatology of models
